

Design methodology for automotive steel wheel

Candidate:

Simone Venturini

Tutor:

Prof. Mauro Velardocchia

1. State of the Art

- Tyre behaviour is deeply investigated in literature (MF, FEM, etc.).
- Wheel must follow ETRTO and vehicle manufacturer requirements (impact ISO 7141, cornering, rim rolling, biaxial fatigue test, etc.)
- In vehicle dynamics wheel is mainly considered as a **rigid body**
- Not consistent test benches models when the tyre is present
- Interest in smart, deformable, reconfigurable wheels

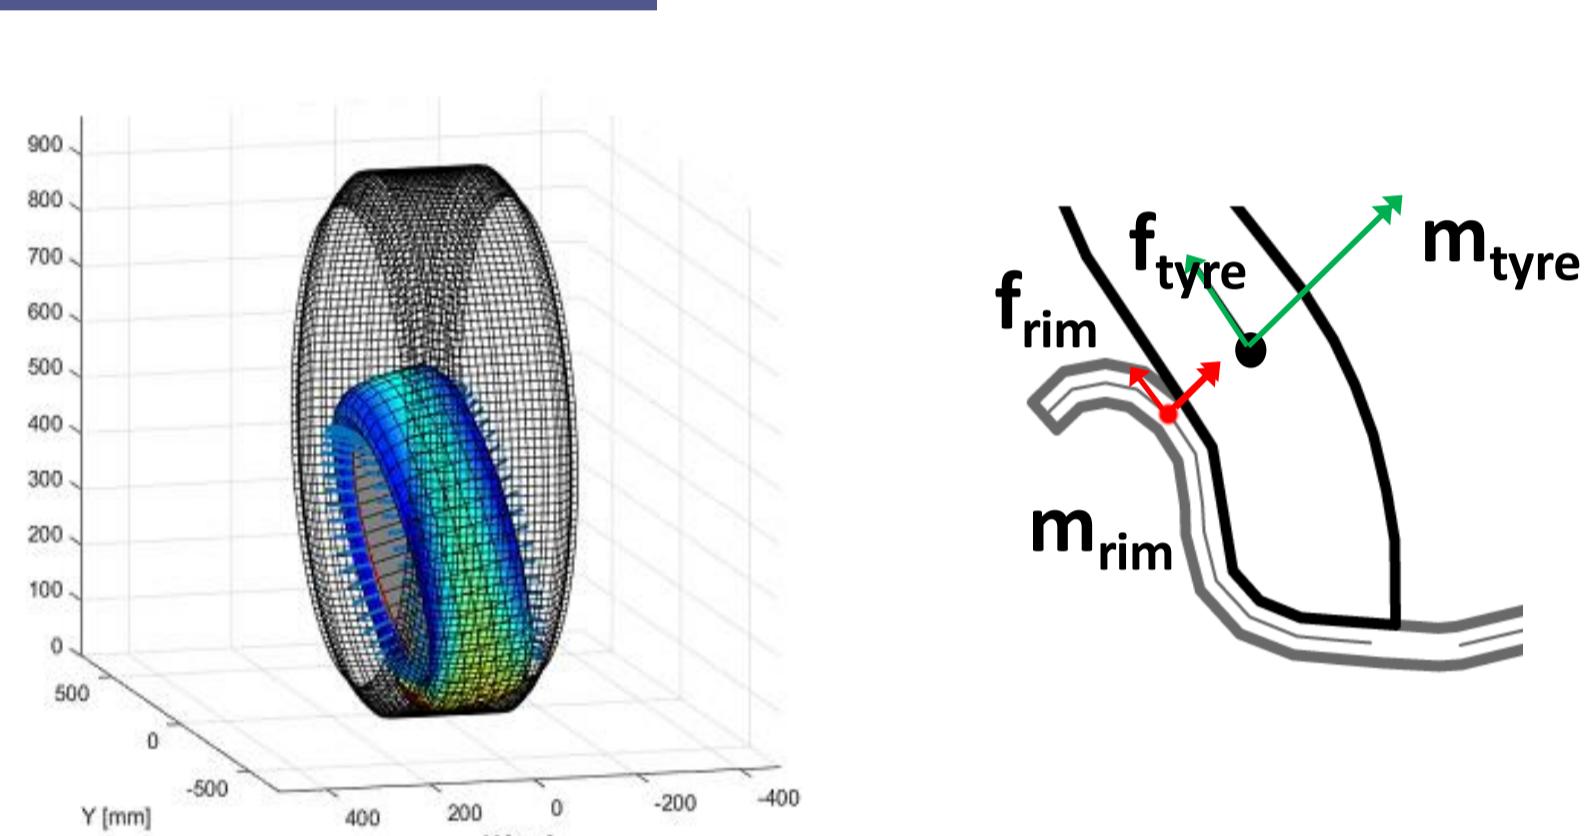

2. Objectives

To develop a **robust model** to describe **static** and **dynamic** behaviour and life assessment of steel wheels in loading conditions obtainable on rim rolling, cornering and biaxial test benches

3. Enriched FE model

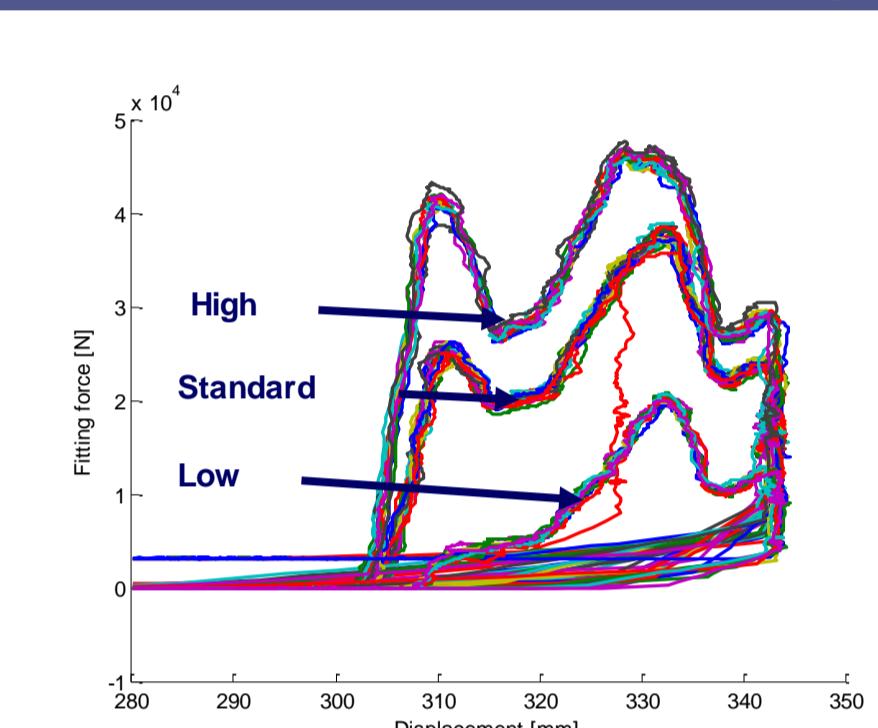

A finite element model is developed, embedding features to better describe critical zones for stress concentration and variation

Load profiles

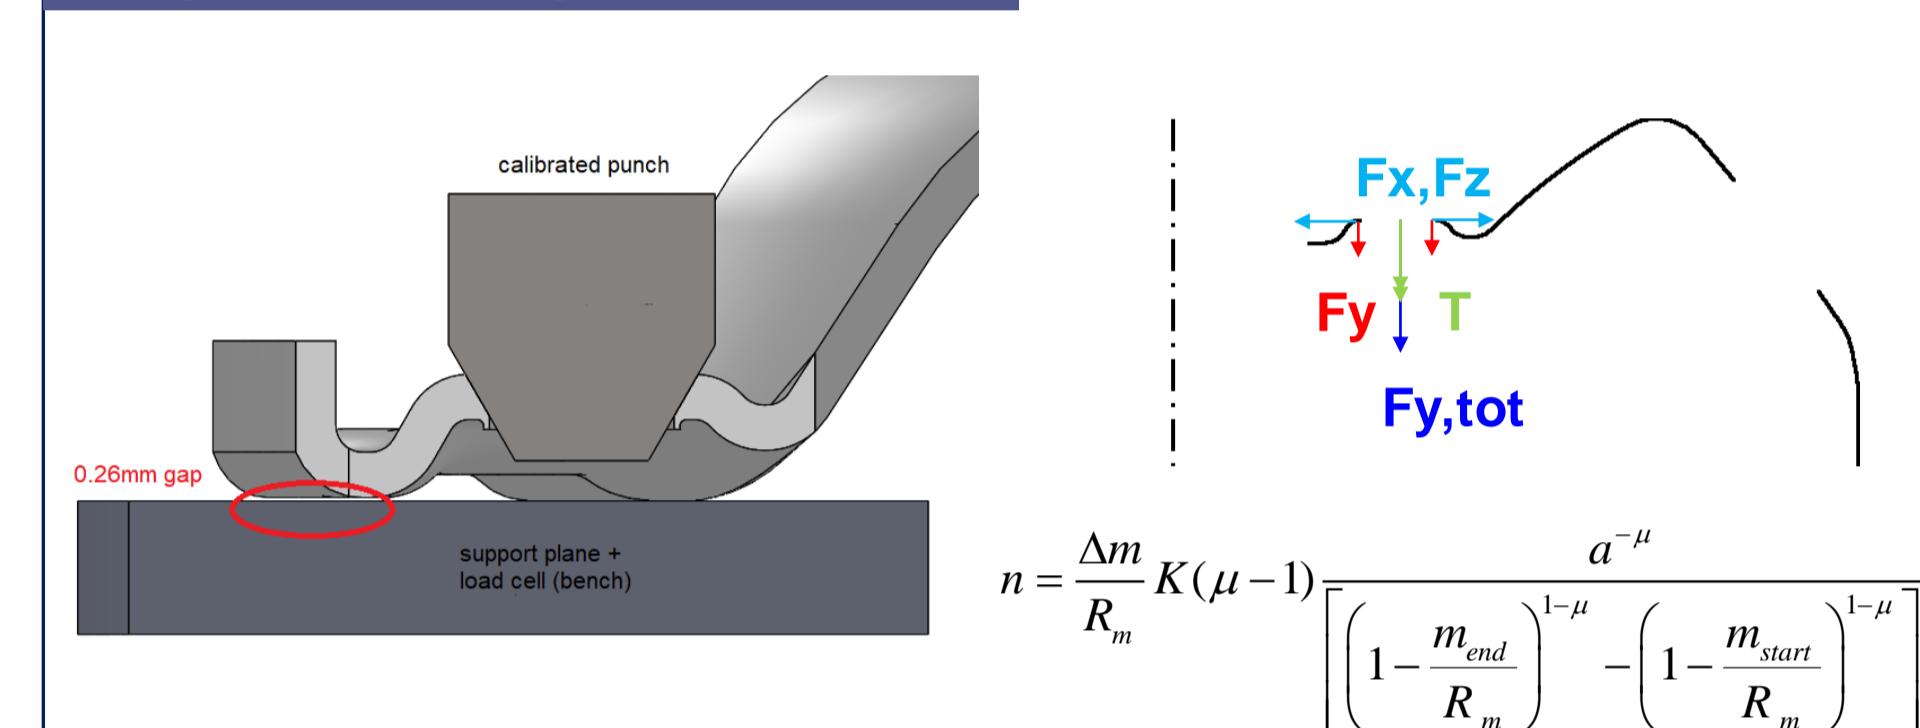

- CDTire deformable tyre analysis
- Loads are interpolated to fit wheel mesh

Disc-to-Rim fitting

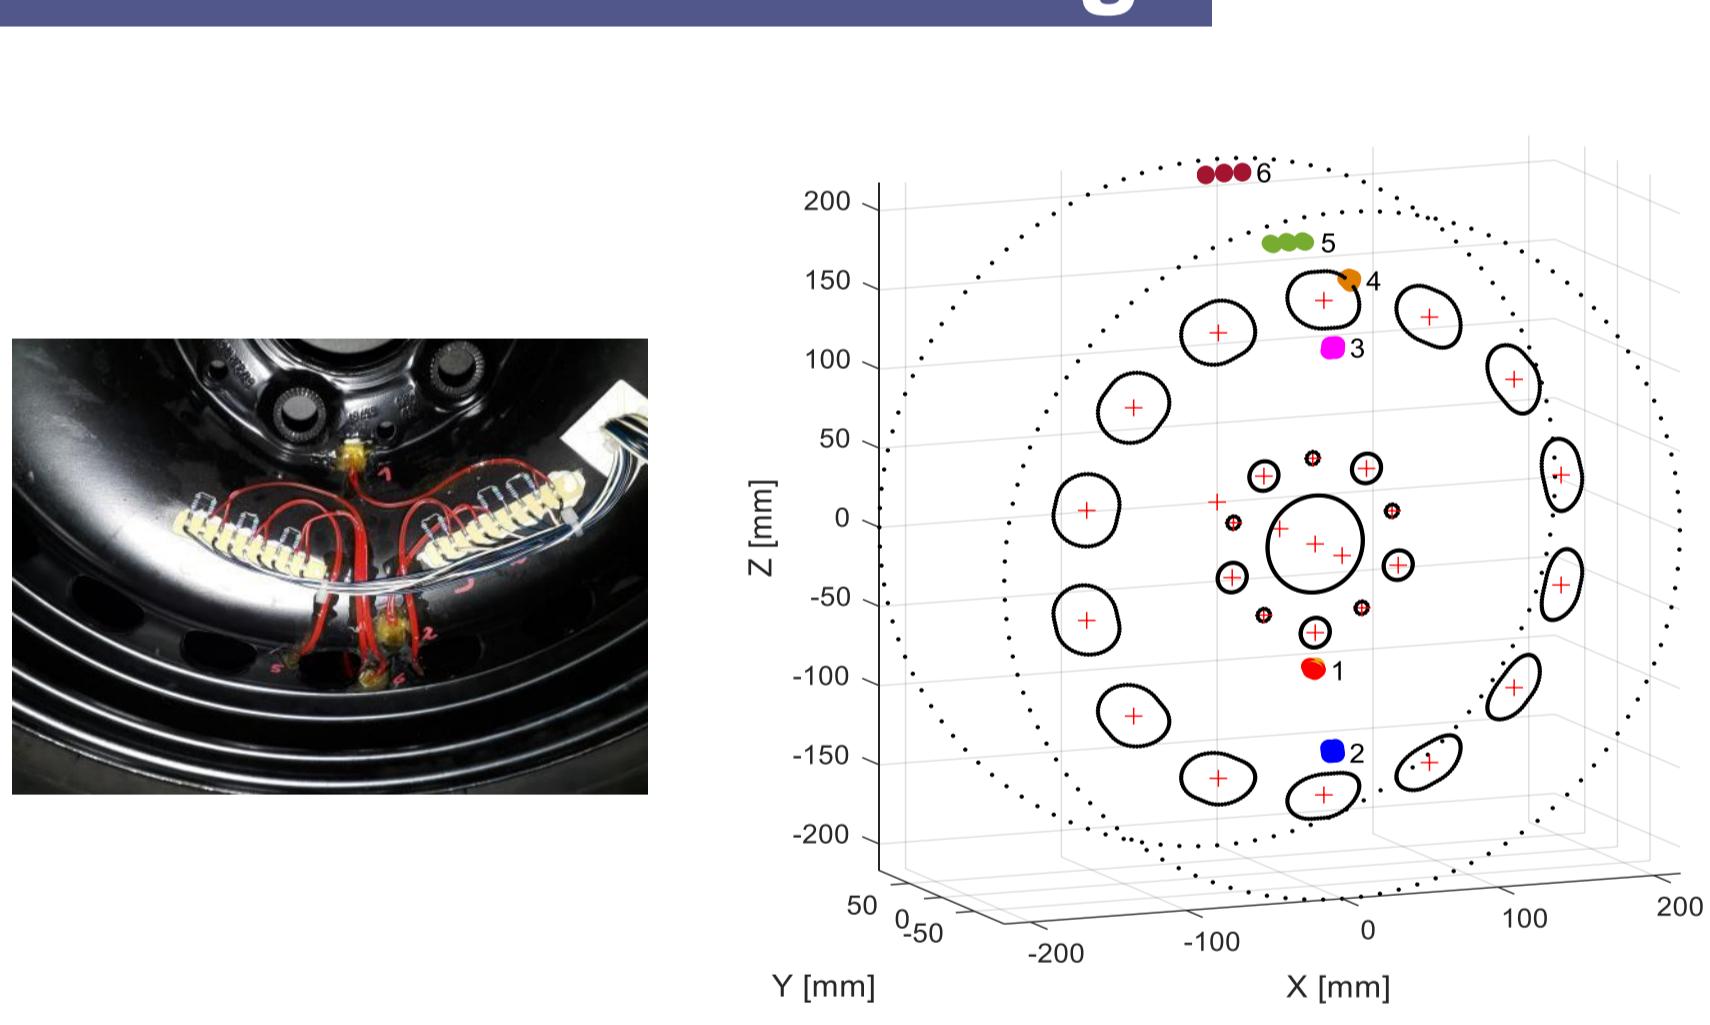

- Fitting force depends on geometry variance
- Fitting effect is estimated through PCE surrogate models based on **stiffening effect** on structural properties

Tightening torque

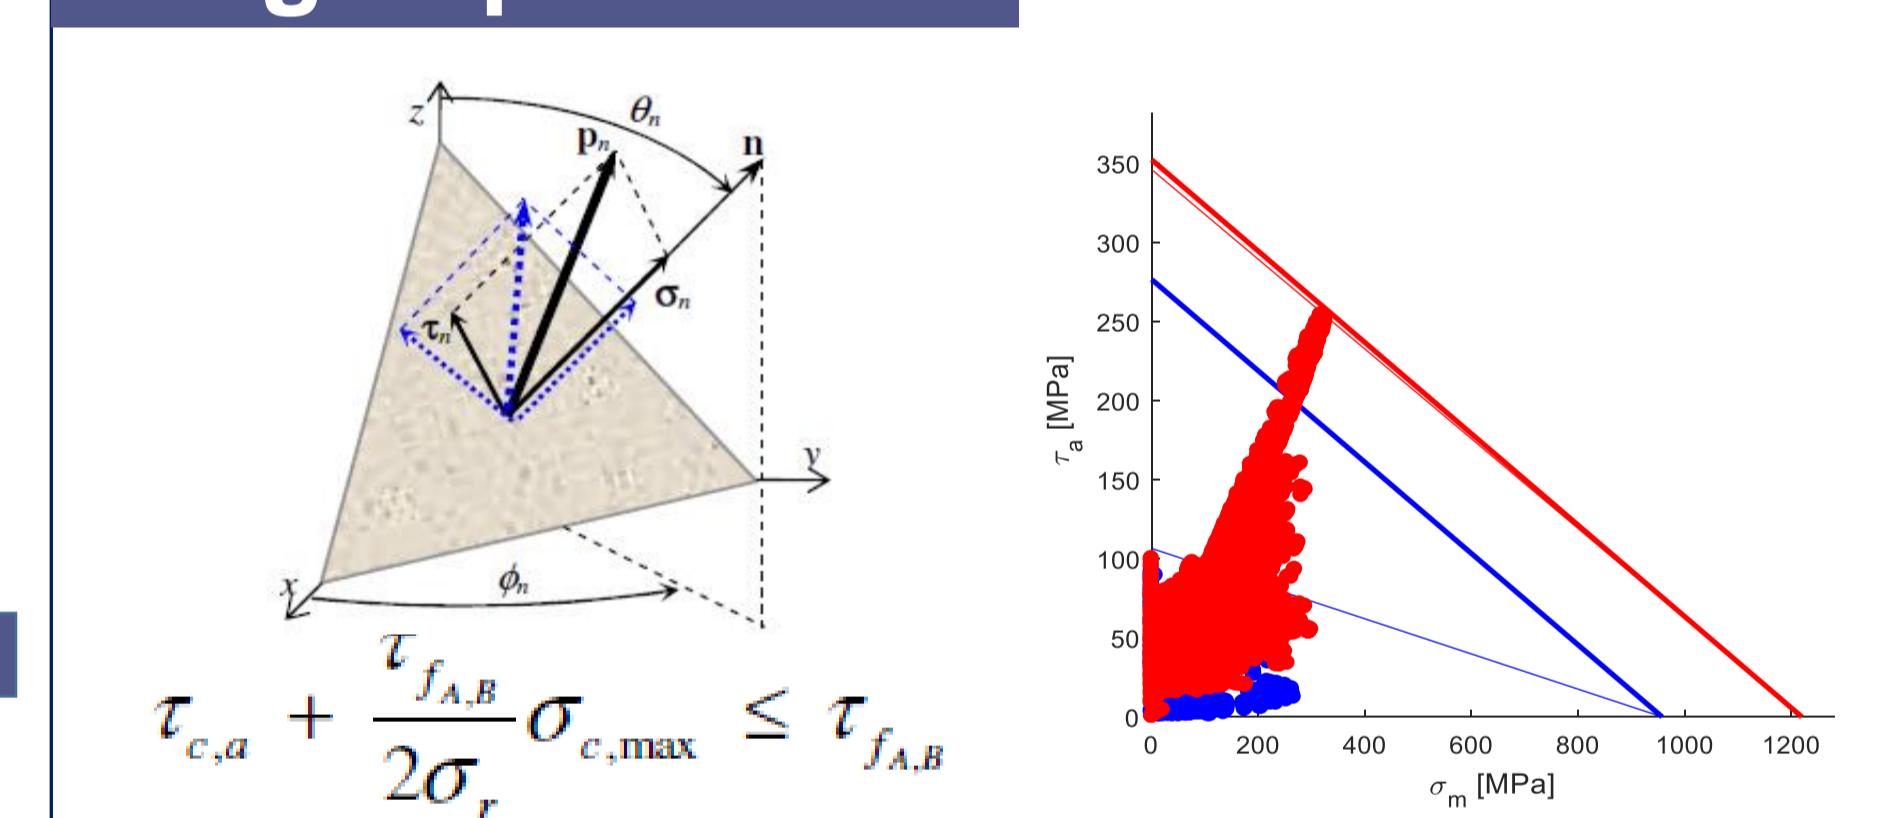

- Tightening torque is converted in equivalent nodal force
- Tightening loss effect on life is performed through integrated Miner rule

Stress-strain monitoring

- Strain gage measurements are compared by stress tensor transformation

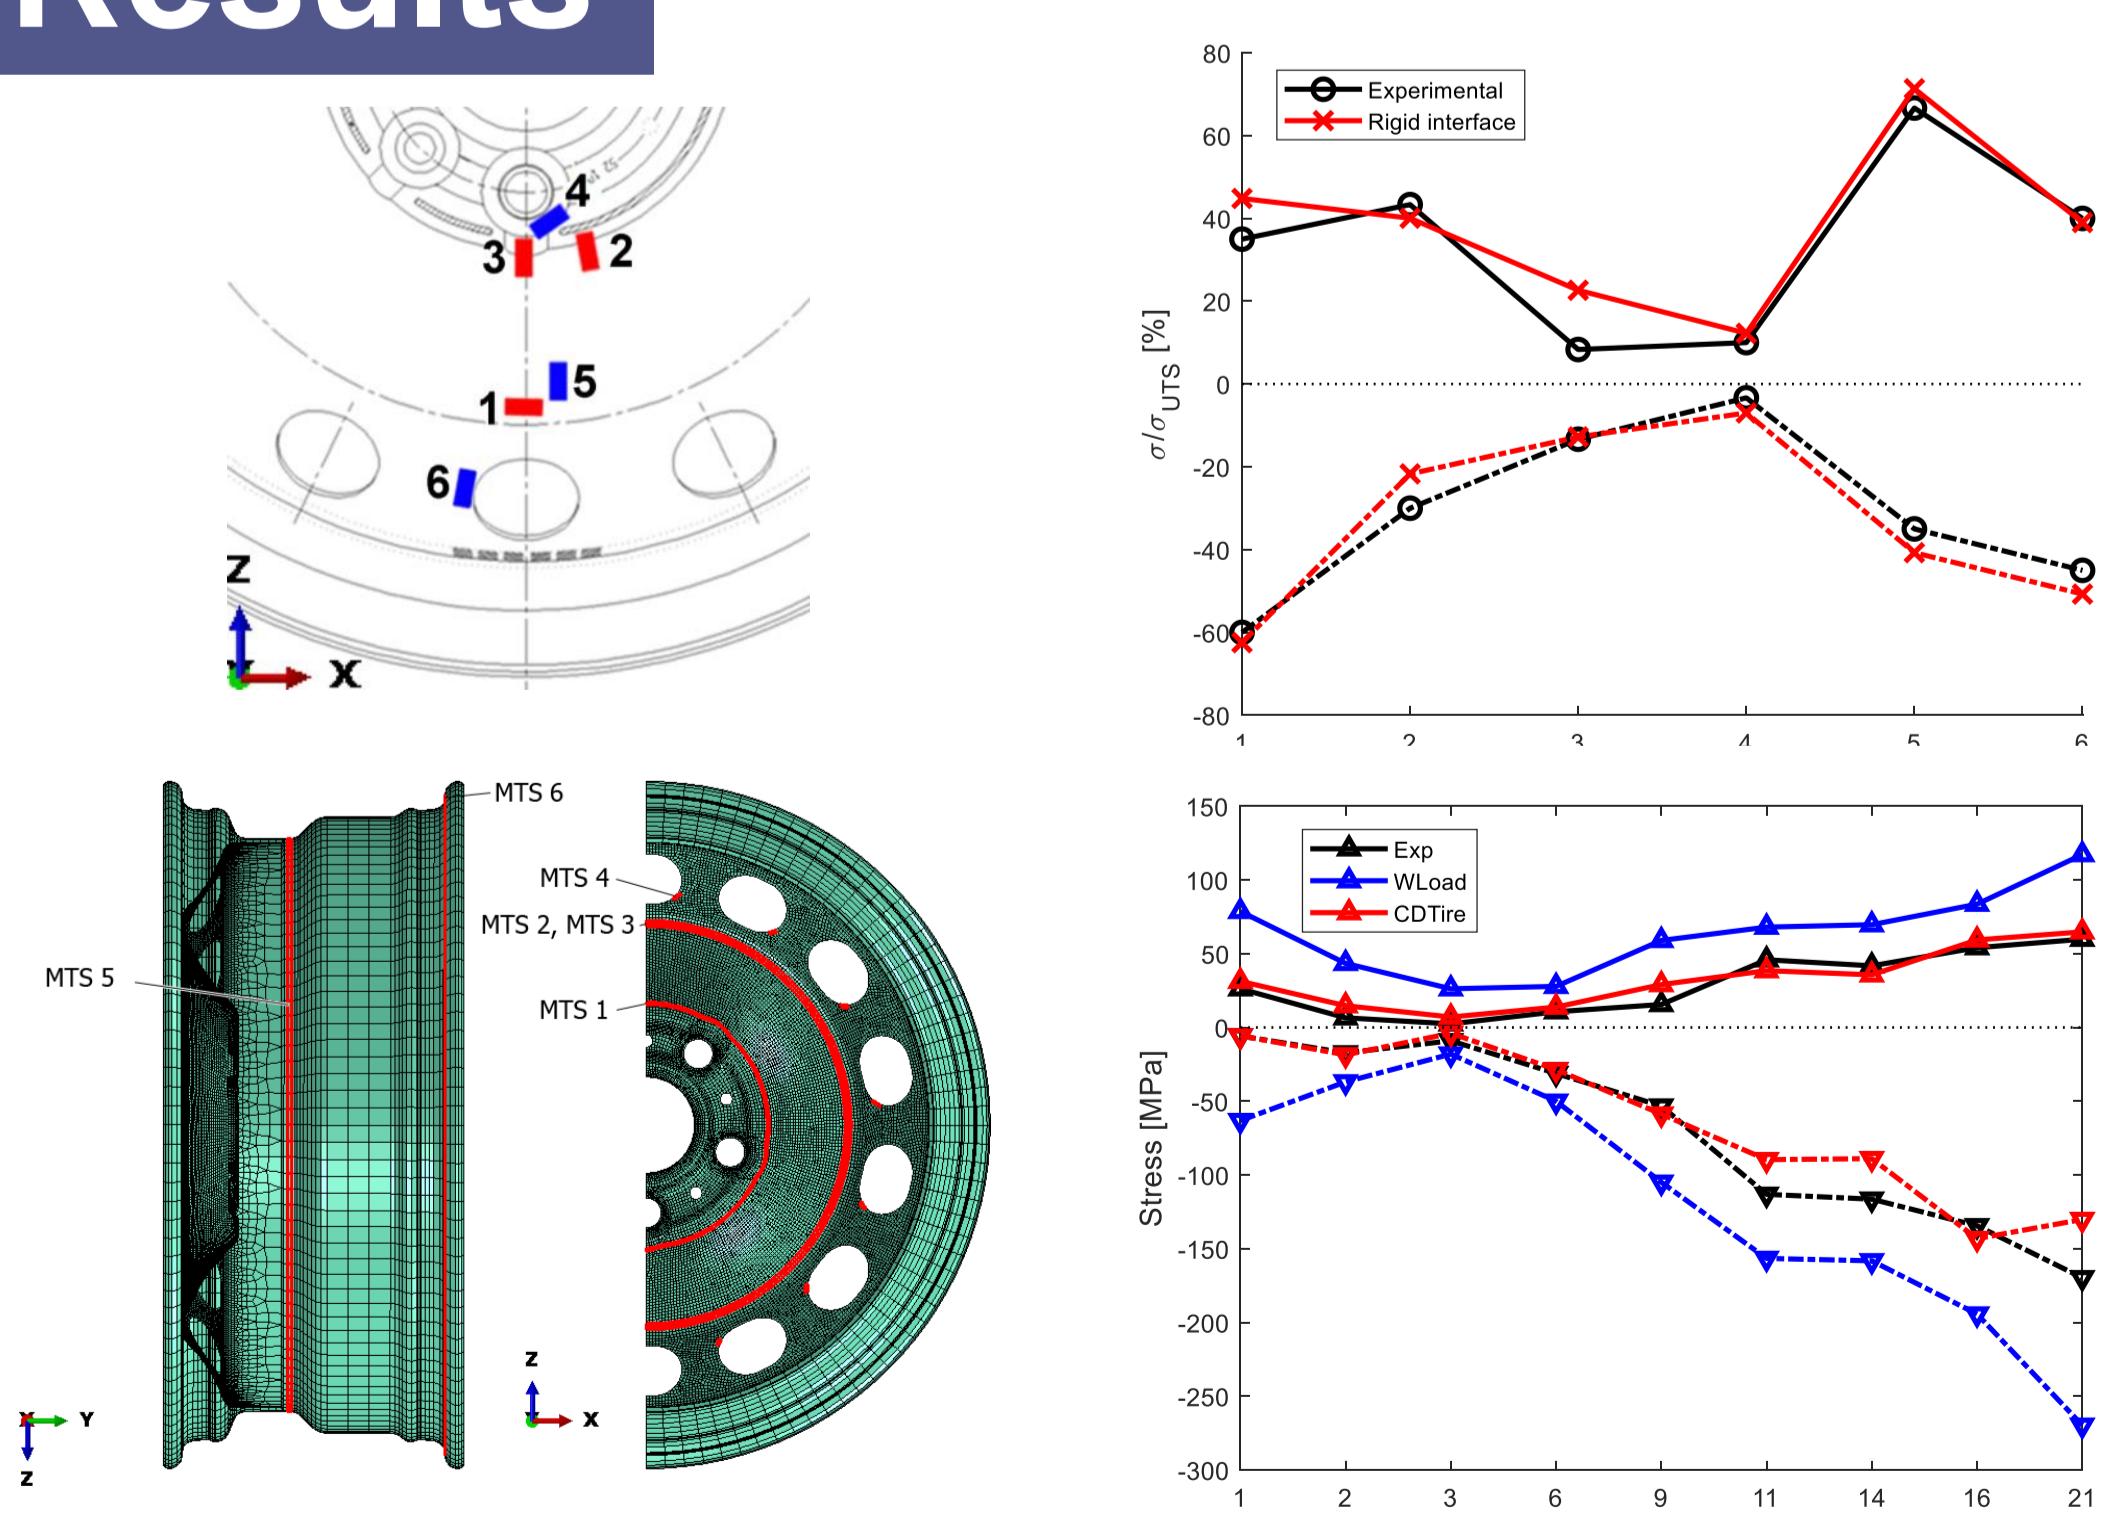

Fatigue prediction

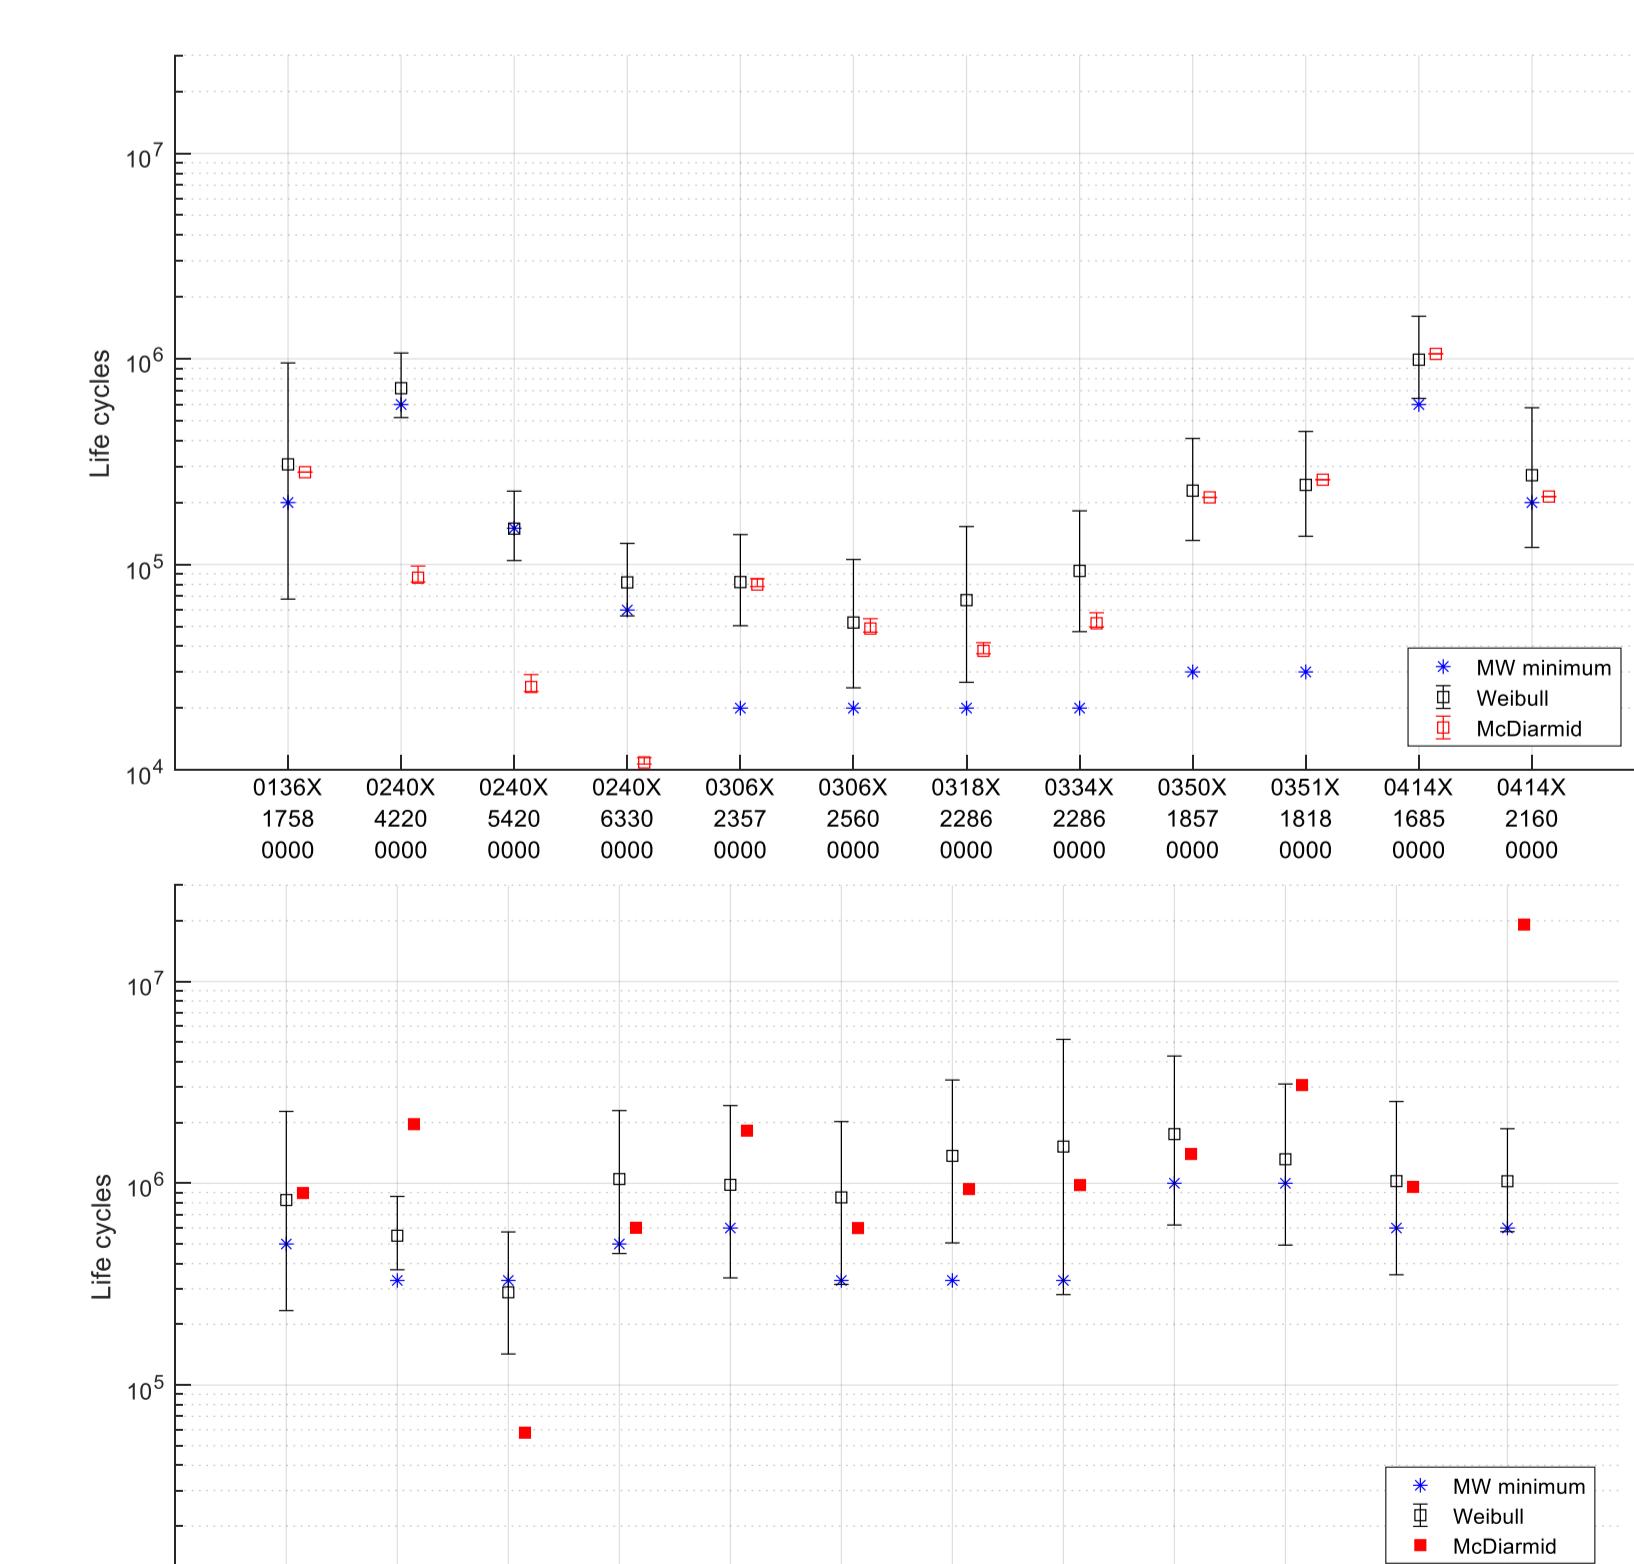

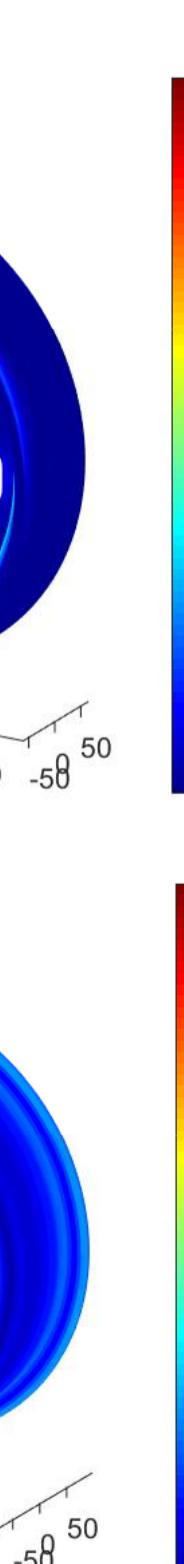

- McDiarmid approach
- Assessment on envelope of elemental stress at Gauss points

4. Results

Strain gage and life cycle comparisons

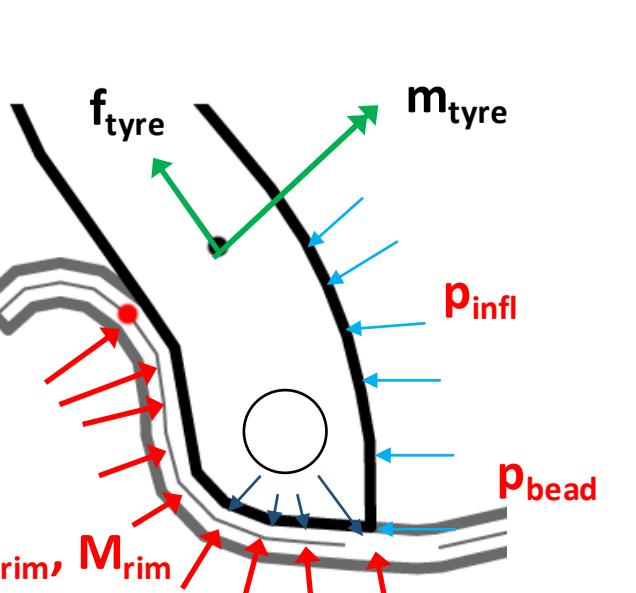

Damage Factor (Inner)

5. Future works

- bead pretension
- inflation pressure
- load field to the middle rim surface
